ART. I.—NOTES ON THE DEBERT COAL FIELD, COLCHESTER
   Co., N. S. BY EDWIN GILPIN, JR., A. M., F. G. S.,
   F. R. S. C., INSPECTOR OF MINES.
   (Read 12th Nov., 1883.)

During the past few months a good deal of interest has been
shown in Mining circles over the reported discoveries of coal
seams, of workable size, on the DeBert River, Colchester Co. In
this conclusion the following notes of a brief visit to the ground
may prove interesting to the members of the Institute, and I
only regret that the attention necessarily directed to mines in
operation has prevented me from giving more time to the
problems presented by this practically unknown district.

The presence of coal beds on the DeBert and Chignagoise
Rivers has long been known to the geologist. Gesner, one of the
pioneers of Nova Scotian Geology, writing in 1836, described the
signs of coal at various points along the north side of the Basin
of Minas, from Cape Chignecto to Truro, and remarks, page 129
of his "Geology and Mineralogy of Nova Scotia," that "About
five miles northward of the Lower DeBert bridge the coal
measures of the mountains rise above the gypseous and saliferous
sandstones, and a beautiful section of their strata is made by the
river passing over them. Two small veins of coal have been
intersected, although it is not known what quantity of that
valuable substance is still hidden in the adjacent rocks."

Dr. Dawson, in the second edition of his Acadiaen Geology,
page 264, speaks of the metamorphic slates of the Cobequid
Mountains being succeeded by conglomerates, and then by "coal
measure rocks, consisting of gray sandstones and dark shales,
and a few thin seams of coal, and abundance of leaves of cordaites, and a few calamites and stigmaria."

He further remarks: "We can trace this coal measure back from Advocate Harbour, near Cape Chignecto, to the upper part of the Salmon River of Truro, where it adjoins the carboniferous district of Pictou. It is (generally speaking) much broken and disturbed; and although it widens considerably towards its eastern extremity, it nowhere attains a great development, either in horizontal extent, or in the magnitude of its coal seams." From Advocate Harbour to Partridge Island the belt contains contorted shales and sandstones yielding a few fossil plants, scales of fishes, and shells of Naiadites. Mr. Matthew Jones, a member of this Institute, some years ago found in these strata footprints of a large reptilian animal, referable to the genus sauropus. Similar shales and sandstones outcrop on the banks of the various rivers falling into the Basin of Minas, and show beds of bituminous limestone, with cyprids and fish scales, fireclays, clay ironstones, etc., and yield characteristic fossil plants of several of the species found in the Joggins section.

In the same work Dr. Dawson has discussed the physical conditions which governed the deposition of the coal and associated carboniferous measures of the district. The evidence of the foldings of the carboniferous of the north side of the Basin of Minas, plainly given by the various river sections, leads to the anticipation that the coal measure band may prove disturbed. The longitudinal foldings are useful to the prospector, as they bring the various coal crops to the surface, and define the limits within which his researches can be carried on with profit. The transverse folding and faults caused by unequal strains, and by the irregularity of the great mountain chain, the determining element, may prove a source of expense to the miner engaged in economic development.

The upper DeBert bridge, on the Londonderry road, appears to be a little to the south of the centre of the Basin in this locality. Following the stream downwards from the bridge the coal beds appear about in the relative order of the section, which is descending geologically speaking:

The first seam met is one on the west side of the River, and it is stated to measure about 2 ft. 6 in. of coal. The nine feet seam, so-called, had not been opened at the time of my visit, and the thickness is that given by the man in charge of the boring. The seam below this is exposed on the west bank of the river, nearly on the line of the seam just referred to as being nine feet thick.

The six feet seam was opened last winter by a short slope, and about 50 tons of coal were extracted. It is stated to have in the centre a band of shaley coal about 9 inches thick. I was unable to verify the dimensions by actual measurement, as all the openings were full of water at the time of my visit, but the outcrop of the bed under the waters of the river apparently confirmed them.

The coal looked unusually well for a crop exposure, and samples selected to form an average gave the following results:—

Coal compact. Cleavage planes very obliquely inclined to each other. Fractures of the coal presented a conchoidal and lustrous appearance. The deposition planes showed a good deal of mineral charcoal. The coal is laminated with numerous bright pitchy layers up to one-half of an inch in thickness. A few films of calc-spar showed in the cleavage planes, and there was very little visible pyrites. Powder dark reddish brown.
ON ANALYSIS (by fast coking.)

Sulphur .................................. 2·648

Coke fairly coherent.

From this analysis it will appear that the coal, although holding more sulphur than is usually found in the coals of Nova Scotia proper, is of good quality, and similar in general composition to that mined at Spring Hill.

About 100 feet below the 6 feet seam is a bed of conglomerate, having a dip to the north similar to that of the section given above. The conglomerate appeared to be about 150 feet wide on the river, and to grow broader to the westward. Where exposed on a small brook about \( \frac{1}{4} \) of a mile west of the river, it presented a double dip S 5° W and N 10° W, apparently forming the saddle of an anticlinal, and was overlaid to the south by gray shaley sandstones dipping S 5° W and at an angle of 25°.

On the north side of the conglomerate, on the brook, at about the same distance from it as the so-called nine foot seam is on the river, an imperfect exposure of coal is met presenting the following section:

About 100 feet further up the brook a four feet seam of coal is said to have been proved by a bore hole.

About 100 yards above the bridge is an exposure of measures holding a seam of coal about 18 inches thick, and running nearly at right angles to the course of the seams already described. From this it would appear that the beds exposed on the river are
at the eastern apex of a subordinate basin formed by transverse folding.

Should further research show that at this point the seams referred to maintain their size, and extend in a form permitting of economic exploitation, the discoveries are of great importance. The search for similar seams may then reasonably be made at other points along the coal band, and certainly the areas of the Minas Basin coal field is large enough to allow a hope that in the future it may be added to the list of our productive districts.

(Read 14th Jan., 1884.)

For a number of years the presence of these ores in Cape Breton was recorded only by the mineralogist. Recently, however, deposits of economic value have been found and worked. The ores of manganése occur, in Nova Scotia proper, in strata of Lower Carboniferous age, occupying a horizon low down in the Marine Limestone formation. The late Dr. How, in a paper read before this Institute some years ago, gave an interesting account of these minerals as they occur and are worked in Hants County. This evening I purpose merely to draw the attention of the Institute to their occurrence in Cape Breton, an interesting fact, as the knowledge of their presence in workable amounts in the Loch Lomond district will lead to a search for them in other parts of the Island. In all probability, the wide extent of the Cape Breton Limestones will before long afford several localities containing deposits worthy of the miner's attention. My notes are from a visit to the mine, and from information kindly furnished me by Mr. Fletcher, of the Geological Survey of Canada, who made a detailed survey of this district summer before last. The geological features of this part of Cape Breton are represented by a band of millstone grit extending from Mira River,
